- 2 Naturalising Geometry
- 3 Analysis and Synthesis
- 4 Conclusions

Lobachevsky's *Elements of Geometry*

Lobachevsky was a professor of mathematics (since 1814) and later a rector (in 1827–1846) in a recently founded (in 1804) provincial Russian university in Kazan. In this capacity he was supposed to produce, primarily, teaching and learning materials rather than the original research.

Research was (and still is) mostly reserved for the Russian Academy of Sciences, which also supervised teaching and the eventual research in the universities. Lobachevsky's attempts to get an approval from the Academy were not successful (the negative report by Mikhail Ostrogradsky in 1832).

Lobachevsky in 1839 as the Rector of Kazan University

Lobachevsky's *Elements of Geometry*

This is why the major part of Lobachevsky's written output has the textbook form and titled accordingly as the *Elements of Geometry* or *Foundations of Geometry* (Начала геометрии). It includes

- *New Foundations of Geometry* of 1835–1838.

Lobachevsky's *Elements of Geometry*

This is why the major part of Lobachevsky's written output has the textbook form and titled accordingly as the *Elements of Geometry* or *Foundations of Geometry* (Начала геометрии). It includes

- *Foundations of Geometry* of 1819 (lost);
- *Geometry* of 1823 (lost and found);
- *On Foundations of Geometry* of 1829–1830;
- *New Foundations of Geometry* of 1835–1838.

The title *Начала* used by Lobachevsky was first used for translating the title of Euclid's *Elements* by Thoma Petrushevsky in 1819 and since then became standard.

Lobachevsky adversus Euclid

Lobachevsky's attempt to revise the foundations of geometry naturally inscribes into the long-term Euclidean tradition. But Lobachevsky's revision of this tradition is very radical and it goes **far beyond** dropping the Fifth Postulate and developing a more general (non-Euclidean) geometrical theory.

- 2 **Naturalising Geometry**
- 3 Analysis and Synthesis
- 4 Conclusions

Geometry as a Natural Science

In Lobachevsky's view, Geometry is a proper part of Natural Science and Engineering. In this respect he follows d'Alembert in the *Encyclopedia* and the d'Alembert-style French geometry textbooks by Clairaut (1741), Bézou (1781), Legendre (1794), Lacroix (1795), Monge (1795).

Geometry as a Natural Science

In Lobachevsky's view, Geometry is a proper part of Natural Science and Engineering. In this respect he follows d'Alembert in the *Encyclopedia* and the d'Alembert-style French geometry textbooks by Clairaut (1741), Bézou (1781), Legendre (1794), Lacroix (1795), Monge (1795).

In the continuing debate between the defenders of Euclid in mathematics education (like Petrushevsky) and the promoters of the new d'Alembertian approach Lobachevsky definitely takes the latter side. Following in d'Alembert's steps Lobachevsky does not give his geometrical theory any axiomatic form.

Naturalising Foundations

Lobachevsky's discovery of the Hyperbolic geometry was a byproduct of his broader project of building Geometry on the naturalistic foundations, which might better connect this mathematical discipline to empirical measurements (including the geodesic and astronomical measurements).

Naturalising Foundations

Lobachevsky's discovery of the Hyperbolic geometry was a byproduct of his broader project of building Geometry on the naturalistic foundations, which might better connect this mathematical discipline to empirical measurements (including the geodesic and astronomical measurements).

Lobachevsky hoped to achieve this goal by avoiding traditional Euclidean concepts like the “length without breadth”, which in his view were exceedingly abstract and detached from the sensual experience.

Naturalising Foundations

Lobachevsky's discovery of the Hyperbolic geometry was a byproduct of his broader project of building Geometry on the naturalistic foundations, which might better connect this mathematical discipline to empirical measurements (including the geodesic and astronomical measurements).

Lobachevsky hoped to achieve this goal by avoiding traditional Euclidean concepts like the “length without breadth”, which in his view were exceedingly abstract and detached from the sensual experience.

In addition to the foundations of Hyperbolic geometry this project included an early form of Dimension theory, which was not quite successful.

“[T]he conceptual obscurity [in the traditional foundations of Geometry] is produced by the abstractness, which is redundant in the actual measurements and hence also unnecessary in the theory itself. Surfaces, lines and points as they are [usually] defined in Geometry exist only in our imagination while the [actual] measurement of surfaces and lines is done using bodies.

“[T]he conceptual obscurity [in the traditional foundations of Geometry] is produced by the abstractness, which is redundant in the actual measurements and hence also unnecessary in the theory itself. Surfaces, lines and points as they are [usually] defined in Geometry exist only in our imagination while the [actual] measurement of surfaces and lines is done using bodies.

This is why it is appropriate to talk about surfaces, lines and points only as so far as these concepts are used in the actual measurement.” (*The New Foundations, Intro*)

Historical error

The popular idea that the emergence of Non-Euclidean geometry was historically related to a detachment of the Pure Mathematics from empirical sciences is a myth.

Historical error

The popular idea that the emergence of Non-Euclidean geometry was historically related to a detachment of the Pure Mathematics from empirical sciences is a myth.

This myth has been designed in the early 20th century when Lobachevsky's geometrical theory was given an axiomatic form by David Hilbert, Henri Poincaré, Jean Dieudonné and others.

- 2 Naturalising Geometry
- 3 Analysis and Synthesis**
- 4 Conclusions

A Reversal of the Epistemic Roles

Lobachevsky shares the view articulated by Condillac in his *Logic* according to which the *Analytic* geometry represents a higher level of mathematical knowledge than the traditional Euclid-style axiomatic *Synthetic* geometry.

A Reversal of the Epistemic Roles

Lobachevsky shares the view articulated by Condillac in his *Logic* according to which the *Analytic* geometry represents a higher level of mathematical knowledge than the traditional Euclid-style axiomatic *Synthetic* geometry.

This is why Lobachevsky avoids using the axiomatic method quite deliberately but not just as a result of his alleged carelessness about logic.

Still a Synthesis

Yet, contrary to Condillac, Lobachevsky grants to the Synthetic geometry an auxiliary pedagogical role, and produces his many versions of *Foundations of geometry*.

Still a Synthesis

Yet, contrary to Condillac, Lobachevsky grants to the Synthetic geometry an auxiliary pedagogical role, and produces his many versions of *Foundations of geometry*.

But in his *Imaginary geometry* published in 1837 in French in the *Crelle Journal* Lobachevsky opts for a purely Analytic presentation of his theory.

Theoretical error

Considering Lobachevsky's achievements exclusively from an axiomatic viewpoint is not only historical but also a theoretical mistake.

Theoretical error

Considering Lobachevsky's achievements exclusively from an axiomatic viewpoint is not only historical but also a theoretical mistake.

John Milnor in his 1982 paper argues that Lobachevsky's research into the Hyperbolic geometry was not properly understood before the late 1970s when William Thurston generalised some of Lobachevsky's results in his theory of Hyperbolic manifolds.

- 1 Key facts about Nikolai Iv. Lobachevsky (1792–1856)
- 2 Naturalising Geometry
- 3 Analysis and Synthesis
- 4 Conclusions

Conclusion 1

In spite of his striking divergences from the Euclidean tradition (which are by far more significant than in Hilbert's 1899 case!) Lobachevsky, nevertheless, opts for presenting his achievements in the traditional form of the *Elements* !

Conclusion 2

Lobachevsky's project of revising the foundations of geometry in order to make this discipline more tightly connected to natural sciences remains largely open.

Conclusion 2

Lobachevsky's project of revising the foundations of geometry in order to make this discipline more tightly connected to natural sciences remains largely open.

Recent attempts to develop Quantum geometry and akin geometrical theories motivated by Physics are very much in Lobachevsky's spirit.

Conclusion 2

Lobachevsky's project of revising the foundations of geometry in order to make this discipline more tightly connected to natural sciences remains largely open.

Recent attempts to develop Quantum geometry and akin geometrical theories motivated by Physics are very much in Lobachevsky's spirit.

To repeat, the popular idea that the emergence of non-Euclidean geometries in the 19th century marks a detachment of Geometry from Physics and other natural sciences (defended, in particular, by Dieudonné and Stone in the 1960s) is erroneous both historically and theoretically.
